

# Recap | Front End

## Step 1

You need to reproduce the **exact same** page that you have on: <https://news.ycombinator.com/> in HTML and CSS.

You can use whatever framework or tools (LESS, Sass, Stylus, Webpack, Gulp...) you want, but the final page should have exactly the same design that the website.

## Step 2

Your page need to be composed only by four component:

- a component that represent the: header (orange bar on top)
- a component that represent the: list of articles
  - a component that represent: an article (should be inside the list component)
- a component that represent the: footer (bellow the orange line)

You can use whatever framework or tools (VanillaJS, Angular 1/2+, VueJS, React, Webpack, Gulp...) you want, but the final page should have exactly the same design that the website with the four components on it.

## Step 3

Using the public API of HackerNews available here (<https://github.com/HackerNews/API>), you should retrieve the real articles and display them in the same way that the website. The different events related to the different links should have the same actions triggered when clicking on them.
